Dynamic Cooperative Verification

Marek Chalupa

April 8, 2024, SV-COMP'24

- Multiple tools cooperate on verification of a program

Dynamic cooperative verification

- Multiple tools cooperate on verification of a program
- Tools can be dynamically invoked or destroyed based on the *state of verification*

- Multiple tools cooperate on verification of a program
- Tools can be dynamically invoked or destroyed based on the *state of verification*
 - E.g., when a new reachable location or state is discovered, or
 - a tool has no progress.

- Multiple tools cooperate on verification of a program
- Tools can be dynamically invoked or destroyed based on the *state of verification*
 - E.g., when a new reachable location or state is discovered, or
 - a tool has no progress.
- Tools share their findings continuously in real-time

- Tools can be dynamically invoked or destroyed based on the *state of verification*
 - E.g., when a new reachable location or state is discovered, or
 - a tool has no progress.
- Tools share their findings continuously in real-time

Runtime monitoring

- Every verifier (but also compilers and other programs) is a *task*

- Every verifier (but also compilers and other programs) is a *task*
- When a task finishes, it either yields a result or it *rewrites* itself into a new task(s).

- Every verifier (but also compilers and other programs) is a *task*
- When a task finishes, it either yields a result or it *rewrites* itself into a new task(s).
- Tasks emit events that other tasks can listen to
 - a task started, finished
 - lines on `stdout` or `stderr`
 - invariants, reached states – requires instrumentation of the tools
