USER DOCUMENTATION

GALAHAD Optimization Library version 5.1

## 1 SUMMARY

Given real  $n$  by  $n$  symmetric matrices  $\mathbf{H}$  and  $\mathbf{M}$  (with  $\mathbf{M}$  positive definite), real  $n$  vectors  $\mathbf{c}$  and  $\mathbf{o}$ , and scalars  $\sigma \geq 0$ ,  $\epsilon \geq 0$  and  $f_0$ , this package finds an **approximate minimizer of the regularised objective function**

$$\frac{1}{2}\mathbf{x}^T\mathbf{H}\mathbf{x} + \mathbf{c}^T\mathbf{x} + f_0 + \frac{1}{p}\sigma[\|\mathbf{x} + \mathbf{o}\|_{\mathbf{M}}^2 + \epsilon]^{p/2},$$

where  $\|\mathbf{v}\|_{\mathbf{M}} = \sqrt{\mathbf{v}^T\mathbf{M}\mathbf{v}}$  is the  $\mathbf{M}$ -norm of  $\mathbf{v}$ . This problem commonly occurs as a subproblem in nonlinear optimization calculations involving cubic regularisation. The method may be suitable for large  $n$  as no factorization of  $\mathbf{H}$  is required. Reverse communication is used to obtain matrix-vector products of the form  $\mathbf{H}\mathbf{z}$ ,  $\mathbf{M}^{-1}\mathbf{z}$  and, perhaps,  $\mathbf{M}\mathbf{z}$ .

**ATTRIBUTES — Versions:** GALAHAD\_GLRT\_single, GALAHAD\_GLRT\_double. **Uses:** GALAHAD\_SYMBOLS, GALAHAD\_SPACE, GALAHAD\_RAND, GALAHAD\_NORMS, GALAHAD\_GLTR, GALAHAD\_ROOTS, GALAHAD\_SPECFILE, \*TTRF. **Date:** November 2007. **Origin:** N. I. M. Gould, Oxford University and Rutherford Appleton Laboratory. **Language:** Fortran 95 + TR 15581 or Fortran 2003.

## 2 HOW TO USE THE PACKAGE

The package is available with single, double and (if available) quadruple precision reals, and either 32-bit or 64-bit integers. Access to the 32-bit integer, single precision version requires the USE statement

```
USE GALAHAD_GLRT_single
```

with the obvious substitution GALAHAD\_GLRT\_double, GALAHAD\_GLRT\_quadruple, GALAHAD\_GLRT\_single\_64, GALAHAD\_GLRT\_double\_64 and GALAHAD\_GLRT\_quadruple\_64 for the other variants.

If it is required to use more than one of the modules at the same time, the derived types GLRT\_control\_type, GLRT\_inform\_type, GLRT\_data\_type, (Section 2.2) and the subroutines GLRT\_initialize, GLRT\_solve, GLRT\_terminate (Section 2.3) and GLRT\_read\_specfile (Section 2.7) must be renamed on one of the USE statements.

### 2.1 Real and integer kinds

We use the terms integer and real to refer to the fortran keywords REAL(rp\_) and INTEGER(ip\_), where rp\_ and ip\_ are the relevant kind values for the real and integer types employed by the particular module in use. The former are equivalent to default REAL for the single precision versions, DOUBLE PRECISION for the double precision cases and quadruple-precision if 128-bit reals are available, and correspond to rp\_ = real32, rp\_ = real64 and rp\_ = real128 respectively as defined by the fortran iso\_fortran\_env module. The latter are default (32-bit) and long (64-bit) integers, and correspond to ip\_ = int32 and ip\_ = int64, respectively, again from the iso\_fortran\_env module.

### 2.2 The derived data types

Three derived data types are accessible from the package.

**All use is subject to the conditions of a BSD-3-Clause License.**

See <http://galahad.rl.ac.uk/galahad-www/cou.html> for full details.

### 2.2.1 The derived data type for holding control parameters

The derived data type `GLRT_control_type` is used to hold controlling data. Default values may be obtained by calling `GLRT_initialize` (see Section 2.3.1). The components of `GLRT_control_type` are:

`error` is a scalar variable of type `INTEGER(ip_)`, that holds the stream number for error messages. Printing of error messages in `GLRT_solve` and `GLRT_terminate` is suppressed if `error ≤ 0`. The default is `error = 6`.

`out` is a scalar variable of type `INTEGER(ip_)`, that holds the stream number for informational messages. Printing of informational messages in `GLRT_solve` is suppressed if `out < 0`. The default is `out = 6`.

`print_level` is a scalar variable of type `INTEGER(ip_)`, that is used to control the amount of informational output which is required. No informational output will occur if `print_level ≤ 0`. If `print_level = 1` a single line of output will be produced for each iteration of the process. If `print_level ≥ 2` this output will be increased to provide significant detail of each iteration. The default is `print_level = 0`.

`itmax` is a scalar variable of type `INTEGER(ip_)`, that holds the maximum number of iterations which will be allowed in `GLRT_solve`. If `itmax` is set to a negative number, it will be reset by `GLRT_solve` to  $n$ . The default is `itmax = -1`.

`extra_vectors` is a scalar variable of type `INTEGER(ip_)`, that specifies the number of additional vectors of length  $n$  that will be allocated to try to speed up the computation during the second pass. The default is `extra_vectors = 0`.

`stopping_rule` is a scalar variable of type `INTEGER(ip_)`, that flags the stopping rule to be used (see `stop_relative` and `stop_absolute` below). Appropriate values are in the range  $[0, 2]$ , and any value outside this range will be interpreted as 0. The default is `stopping_rule = 0`.

`freq` is a scalar variable of type `INTEGER(ip_)`, that defines the frequency at which the tridiagonal subproblem will be solved. Specifically, the subproblem will be solved on iterations  $k = 1 + \text{freq} * i$ , for  $i = 1, 2, \dots$ . If `itmax` is  $\leq 1$ , it will be reset by `GLRT_solve` to 1. The default is `freq = 1`.

`unitm` is a scalar variable of type default `LOGICAL`, that must be set `.TRUE.` if the matrix **M** is the identity matrix, and `.FALSE.` otherwise. The default is `unitm = .TRUE..`

`space_critical` is a scalar variable of type default `LOGICAL`, that may be set `.TRUE.` if the user wishes the package to allocate as little internal storage as possible, and `.FALSE.` otherwise. The package may be more efficient if `space_critical` is set `.FALSE..` The default is `space_critical = .FALSE..`

`deallocate_error_fatal` is a scalar variable of type default `LOGICAL`, that may be set `.TRUE.` if the user wishes the package to return to the user in the unlikely event that an internal array deallocation fails, and `.FALSE.` if the package should be allowed to try to continue. The default is `deallocate_error_fatal = .FALSE..`

`stop_relative` and `stop_absolute` are scalar variables of type `REAL(rp_)`, that holds the relative and absolute convergence tolerances (see Section 4). The computed solution **x** is accepted by `GLRT_solve` if the computed value of  $\|\mathbf{H}\mathbf{x} + \lambda\mathbf{M}\mathbf{x} + \mathbf{c}\|_{\mathbf{M}^{-1}}$  is less than or equal to  $\max(\mathbf{v}\|\mathbf{c}\|_{\mathbf{M}^{-1}} * \text{stop\_relative}, \text{stop\_absolute})$ , where  $\lambda = \sigma[\|\mathbf{x} + \mathbf{o}\|_{\mathbf{M}}^2 + \epsilon]^{p/2-1}$  and  $\mathbf{v}$  depends on the stopping rule selected by `stopping_rule`: for `stopping_rule = 0`,  $\mathbf{v} = 1$ , for `stopping_rule = 1`,  $\mathbf{v} = \min(1, \|\mathbf{x}\|)$ , and for `stopping_rule = 2`,  $\mathbf{v} = \min(1, \|\mathbf{x}\| / \max(1, \sigma))$ . The defaults are `stop_relative =  $\sqrt{u}$`  and `stop_absolute = 0.0`, where  $u$  is `EPSILON(1.0)` (`EPSILON(1.0D0)` in `GALAHAD_GLRT_double`).

`fraction_opt` is a scalar variable of type default `REAL(rp_)`, that specifies the fraction of the optimal value which is to be considered acceptable by the algorithm. A negative value is considered to be zero, and a value of larger than one is considered to be one. Reducing `fraction_opt` below one will result in a reduction of the computation performed at the expense of an inferior optimal value. The default is `fraction_opt = 1.0`.

---

**All use is subject to the conditions of a BSD-3-Clause License.**

See <http://galahad.rl.ac.uk/galahad-www/cou.html> for full details.

`f_0` is a scalar variable of type default `REAL(rp_)`, that gives the value of the constant term  $f_0$  in the objective function. This value has no effect on the computed minimizer  $\mathbf{x}$ . The default is `f_0 = 0.0`.

`rminvr_zero` is a scalar variable of type default `REAL(rp_)`, that gives the smallest value that the square of the  $\mathbf{M}$ -norm of the gradient of the objective function may be before it is considered to be zero. The default is `rminvr_zero = 10 u`, where  $u$  is `EPSILON(1.0)` (`EPSILON(1.0D0)` in `GALAHAD_GLRT_double`).

`prefix` is a scalar variable of type default `CHARACTER` and length 30, that may be used to provide a user-selected character string to preface every line of printed output. Specifically, each line of output will be prefaced by the string `prefix(2:LEN(TRIM(prefix))-1)`, thus ignoring the first and last non-null components of the supplied string. If the user does not want to preface lines by such a string, they may use the default `prefix = ""`.

### 2.2.2 The derived data type for holding informational parameters

The derived data type `GLRT_inform_type` is used to hold parameters that give information about the progress and needs of the algorithm. The components of `GLRT_inform_type` are:

`status` is a scalar variable of type `INTEGER(ip_)`, that gives the current status of the algorithm. See Sections 2.4 and 2.5 for details.

`alloc_status` is a scalar variable of type `INTEGER(ip_)`, that gives the status of the last internal array allocation or deallocation. This will be 0 if `status = 0`.

`bad_alloc` is a scalar variable of type default `CHARACTER` and length 80, that gives the name of the last internal array for which there were allocation or deallocation errors. This will be the null string if `status = 0`.

`obj` is a scalar variable of type `REAL(rp_)`, that holds the value of the quadratic function  $\frac{1}{2}\mathbf{x}^T\mathbf{H}\mathbf{x} + \mathbf{c}^T\mathbf{x} + f_0$ .

`obj_regularized` is a scalar variable of type `REAL(rp_)`, that holds the value of the regularized objective function  $\frac{1}{2}\mathbf{x}^T\mathbf{H}\mathbf{x} + \mathbf{c}^T\mathbf{x} + f_0 + \frac{1}{p}\sigma[\|\mathbf{x} + \mathbf{o}\|_{\mathbf{M}}^2 + \epsilon]^{p/2}$ .

`multiplier` is a scalar variable of type default `REAL(rp_)`, that holds the value of the multiplier  $\lambda = \sigma[\|\mathbf{x} + \mathbf{o}\|_{\mathbf{M}}^2 + \epsilon]^{p/2-1}$ .

`leftmost` is a scalar variable of type default `REAL(rp_)`, that holds an estimate of the leftmost eigenvalue of the matrix pencil  $(\mathbf{H}, \mathbf{M})$ .

`iter` is a scalar variable of type `INTEGER(ip_)`, that holds the current number of Lanczos vectors used.

`iter_pass2` is a scalar variable of type `INTEGER(ip_)`, that holds the current number of Lanczos vectors used in the second pass.

`negative_curvature` is a scalar variable of type default `LOGICAL`, that is set `.TRUE.` if  $\mathbf{H}$  has been found to be indefinite during the calculation and `.FALSE.` otherwise.

### 2.2.3 The derived data type for holding problem data

The derived data type `GLRT_data_type` is used to hold all the data for a particular problem between calls of `GLRT` procedures. This data should be preserved, untouched, from the initial call to `GLRT_initialize` to the final call to `GLRT_terminate`.

---

**All use is subject to the conditions of a BSD-3-Clause License.**

See <http://galahad.rl.ac.uk/galahad-www/cou.html> for full details.

### 2.3 Argument lists and calling sequences

There are three procedures for user calls (see Section 2.7 for further features):

1. The subroutine `GLRT_initialize` is used to set default values, and initialize private data.
2. The subroutine `GLRT_solve` is called repeatedly to solve the problem. On each exit, the user may be expected to provide additional information and, if necessary, re-enter the subroutine.
3. The subroutine `GLRT_terminate` is provided to allow the user to automatically deallocate array components of the private data, allocated by `GLRT_solve`, at the end of the solution process. It is important to do this if the data object is re-used for another problem since `GLRT_initialize` cannot test for this situation, and any existing associated targets will subsequently become unreachable.

We use square brackets [ ] to indicate OPTIONAL arguments.

#### 2.3.1 The initialization subroutine

Default values are provided as follows:

```
CALL GLRT_initialize( data, control, inform )
```

`data` is a scalar `INTENT(INOUT)` argument of type `GLRT_data_type` (see Section 2.2.3). It is used to hold data about the problem being solved.

`control` is a scalar `INTENT(OUT)` argument of type `GLRT_control_type` (see Section 2.2.1). On exit, `control` contains default values for the components as described in Section 2.2.1. These values should only be changed after calling `GLRT_initialize`.

`inform` is a scalar `INTENT(OUT)` argument of type `GLRT_inform_type` (see Section 2.2.2). A successful call to `GLRT_initialize` is indicated when the component status has the value 0. For other return values of status, see Section 2.5.

#### 2.3.2 The optimization problem solution subroutine

The optimization problem solution algorithm is called as follows:

```
CALL GLRT_solve( n, p, sigma, X, R, VECTOR, data, control, inform[, eps, 0] )
```

`n` is a scalar `INTENT(IN)` argument of type `INTEGER(ip_)`, that must be set to the number of unknowns,  $n$ . **Restriction:**  $n > 0$ .

`p` is a scalar `INTENT(IN)` variable of type default `REAL(rp_)`, that must be set on initial entry to the desired order  $p$  of regularisation. **Restriction:**  $p \geq 2$ .

`sigma` is a scalar `INTENT(IN)` variable of type default `REAL(rp_)`, that must be set on initial entry to the value of the weight  $\sigma$  associated with the regularisation term. **Restriction:**  $\sigma \geq 0$ .

`X` is an array `INTENT(INOUT)` argument of dimension  $n$  and type `REAL(rp_)`, that holds an estimate of the solution  $\mathbf{x}$  of the linear system. On initial entry, `X` need not be set. It must not be changed between entries. On exit, `X` contains the current best estimate of the solution.

`R` is an array `INTENT(INOUT)` argument of dimension  $n$  and type `REAL(rp_)`, that is used to hold the gradient  $\mathbf{H}\mathbf{x} + \mathbf{c}$  of the objective function at the current estimate of the solution. On initial entry, `R` must contain the vector  $\mathbf{c}$ . If `inform%status = 5` on exit, it must be reset to  $\mathbf{c}$ ; otherwise it must be left unchanged. On exit, `R` contains the gradient of the objective function at the current best estimate of the solution.

---

**All use is subject to the conditions of a BSD-3-Clause License.**

See <http://galahad.rl.ac.uk/galahad-www/cou.html> for full details.

`VECTOR` is an array `INTENT(INOUT)` argument of dimension `n` and type `REAL(rp_)`, that is used to pass information from and to `GLRT_solve`, as explained in Section 2.4. On initial entry, `VECTOR` need not be set. On exit, the actual content of the array depends on the value of the parameter `inform%status` (see Section 2.4).

`data` is a scalar `INTENT(INOUT)` argument of type `GLRT_data_type` (see Section 2.2.3). It is used to hold data about the problem being solved. It must not have been altered **by the user** since the last call to `GLRT_initialize`.

`control` is a scalar `INTENT(IN)` argument of type `GLRT_control_type`. (see Section 2.2.1). Default values may be assigned by calling `GLRT_initialize` prior to the first call to `GLRT_solve`.

`inform` is a scalar `INTENT(INOUT)` argument of type `GLRT_inform_type` (see Section 2.2.2). On initial entry, the component `status` must be set to 1. The remaining components need not be set. A successful call to `GLRT_solve` is indicated when the component `status` has the value 0. For other return values of `status`, see Sections 2.4 and 2.5.

`eps` is an optional scalar `INTENT(IN)` variable of type default `REAL(rp_)`. If `eps` is `PRESENT`, it must be set on initial entry to the value of the shift  $\epsilon$  associated with the regularisation term. **Restriction:**  $\epsilon \geq 0$ .

`O` is an optional array `INTENT(IN)` variable of type default `REAL(rp_)`. If `O` is `PRESENT`, it must be set on initial entry to the value of the offset  $o$  associated with the regularisation term.

### 2.3.3 The termination subroutine

All previously allocated arrays are deallocated as follows:

```
CALL GLRT_terminate( data, control, inform )
```

`data` is a scalar `INTENT(INOUT)` argument of type `GLRT_data_type` exactly as for `GLRT_solve` that must not have been altered **by the user** since the last call to `GLRT_initialize`. On exit, array components will have been deallocated.

`control` is a scalar `INTENT(IN)` argument of type `GLRT_control_type` exactly as for `GLRT_solve`.

`inform` is a scalar `INTENT(OUT)` argument of type `GLRT_type` exactly as for `GLRT_solve`. Only the component `status` will be set on exit, and a successful call to `GLRT_terminate` is indicated when this component `status` has the value 0. For other return values of `status`, see Section 2.5.

## 2.4 Reverse communication

A positive value of `inform%status` on exit from `GLRT_solve` indicates that the user needs to take appropriate action before re-entering the subroutine. Possible values are:

2. The user must perform the preconditioning operation

$$\mathbf{y} := \mathbf{M}^{-1}\mathbf{z},$$

and recall `GLRT_solve`. The vector  $\mathbf{z}$  is available in the array `VECTOR`, and the result  $\mathbf{y}$  must be placed in `VECTOR`. No argument except `VECTOR` should be altered before recalling `GLRT_solve`. This return can only occur when `control%unitm` is `.FALSE..`

3. The user must perform the matrix-vector product

$$\mathbf{y} := \mathbf{H}\mathbf{z}$$

and recall `GLRT_solve`. The vector  $\mathbf{z}$  is available in the array `VECTOR`, and the result  $\mathbf{y}$  must be placed in `VECTOR`. No argument except `VECTOR` should be altered before recalling `GLRT_solve`.

---

**All use is subject to the conditions of a BSD-3-Clause License.**

See <http://galahad.rl.ac.uk/galahad-www/cou.html> for full details.

4. The user should reset  $\mathbf{R}$  to  $\mathbf{c}$  and recall `GLRT_solve`. No argument except  $\mathbf{R}$  should be altered before recalling `GLRT_solve`.

5. The user must perform the operation

$$\mathbf{y} := \mathbf{M}\mathbf{z},$$

and recall `GLRT_solve`. The vector  $\mathbf{z}$  is available in the array `VECTOR`, and the result  $\mathbf{y}$  must be placed in `VECTOR`. No argument except `VECTOR` should be altered before recalling `GLRT_solve`. This return can only occur when both `control%unitm` is `.FALSE.` and `O` is `PRESENT`.

## 2.5 Warning and error messages

A negative value of `inform%status` on exit from `GLRT_solve` or `GLRT_terminate` indicates that an error has occurred. No further calls should be made until the error has been corrected. Possible values are:

- 1. An allocation error occurred. A message indicating the offending array is written on unit `control%error`, and the returned allocation status and a string containing the name of the offending array are held in `inform%alloc_status` and `inform%bad_alloc` respectively.
- 2. A deallocation error occurred. A message indicating the offending array is written on unit `control%error` and the returned allocation status and a string containing the name of the offending array are held in `inform%alloc_status` and `inform%bad_alloc` respectively.
- 3. (`GLRT_solve` only) One or more of the restrictions  $n > 0$ ,  $\sigma \geq 0$ ,  $\epsilon \geq 0$  or  $p \geq 2$  has been violated.
- 7. (`GLRT_solve` only) The problem is unbounded from below. This can only happen if  $p \leq 2$ . In this case, the problem is unbounded along the arc  $\mathbf{x} + \alpha \mathbf{VECTOR}$  as  $\alpha$  increases.
- 15. (`GLRT_solve` only) The matrix  $\mathbf{M}$  appears not to be positive definite.
- 18. (`GLRT_solve` only) More than `control%itmax` iterations have been performed without obtaining convergence.
- 25. (`GLRT_solve` only) `inform%status` is not  $> 0$  on entry.

## 2.6 Re-entry with a new value of $\sigma$

It commonly happens that, having solved the problem for a particular value of the weight  $\sigma$ , a user now wishes to solve the problem for a different value of  $\sigma$ . Rather than restarting the calculation with `inform%status` = 1, a useful approximation may be found resetting `sigma` to the new required value and  $\mathbf{R}$  to  $\mathbf{c}$ , and recalling `GLRT_solve` with `inform%status` = 6 and the remaining arguments unchanged. This will determine the best solution within the Krylov space investigated in the previous minimization (see Section 4).

## 2.7 Further features

In this section, we describe an alternative means of setting control parameters, that is components of the variable `control` of type `GLRT_control_type` (see Section 2.2.1), by reading an appropriate data specification file using the subroutine `GLRT_read_specfile`. This facility is useful as it allows a user to change `GLRT` control parameters without editing and recompiling programs that call `GLRT`.

A specification file, or `specfile`, is a data file containing a number of "specification commands". Each command occurs on a separate line, and comprises a "keyword", which is a string (in a close-to-natural language) used to identify a control parameter, and an (optional) "value", which defines the value to be assigned to the given control parameter. All keywords and values are case insensitive, keywords may be preceded by one or more blanks but values must not contain blanks, and each value must be separated from its keyword by at least one blank. Values must not contain more

---

**All use is subject to the conditions of a BSD-3-Clause License.**

See <http://galahad.rl.ac.uk/galahad-www/cou.html> for full details.

than 30 characters, and each line of the specfile is limited to 80 characters, including the blanks separating keyword and value.

The portion of the specification file used by `GLRT_read_specfile` must start with a "BEGIN GLRT" command and end with an "END" command. The syntax of the specfile is thus defined as follows:

```
( .. lines ignored by GLRT_read_specfile .. )
BEGIN GLRT
  keyword      value
  .....      .....
  keyword      value
END
( .. lines ignored by GLRT_read_specfile .. )
```

where keyword and value are two strings separated by (at least) one blank. The "BEGIN GLRT" and "END" delimiter command lines may contain additional (trailing) strings so long as such strings are separated by one or more blanks, so that lines such as

```
BEGIN GLRT SPECIFICATION
```

and

```
END GLRT SPECIFICATION
```

are acceptable. Furthermore, between the "BEGIN GLRT" and "END" delimiters, specification commands may occur in any order. Blank lines and lines whose first non-blank character is ! or \* are ignored. The content of a line after a ! or \* character is also ignored (as is the ! or \* character itself). This provides an easy manner to "comment out" some specification commands, or to comment specific values of certain control parameters.

The value of a control parameters may be of three different types, namely integer, logical or real. Integer and real values may be expressed in any relevant Fortran integer and floating-point formats (respectively). Permitted values for logical parameters are "ON", "TRUE", ".TRUE.", "T", "YES", "Y", or "OFF", "NO", "N", "FALSE", ".FALSE." and "F". Empty values are also allowed for logical control parameters, and are interpreted as "TRUE".

The specification file must be open for input when `GLRT_read_specfile` is called, and the associated device number passed to the routine in `device` (see below). Note that the corresponding file is `REWINDED`, which makes it possible to combine the specifications for more than one program/routine. For the same reason, the file is not closed by `GLRT_read_specfile`.

### 2.7.1 To read control parameters from a specification file

Control parameters may be read from a file as follows:

```
CALL GLRT_read_specfile( control, device )
```

`control` is a scalar `INTENT(INOUT)` argument of type `GLRT_control_type` (see Section 2.2.1). Default values should have already been set, perhaps by calling `GLRT_initialize`. On exit, individual components of `control` may have been changed according to the commands found in the specfile. Specfile commands and the component (see Section 2.2.1) of `control` that each affects are given in Table 2.1.

`device` is a scalar `INTENT(IN)` argument of type `INTEGER(ip_)`, that must be set to the unit number on which the specfile has been opened. If `device` is not open, `control` will not be altered and execution will continue, but an error message will be printed on unit `control%error`.

---

**All use is subject to the conditions of a BSD-3-Clause License.**

**See <http://galahad.rl.ac.uk/galahad-www/cou.html> for full details.**

## 2.8 Information printed

If `control%print_level` is positive, information about the progress of the algorithm will be printed on unit `control%out`. If `control%print_level = 1`, a single line of output will be produced for each iteration of the process. This will include the iteration number, the value of the objective function, the  $\mathbf{M}^{-1}$ -norm of its gradient  $\|(\mathbf{H} + \lambda\mathbf{M})\mathbf{x} + \mathbf{c}\|_{\mathbf{M}^{-1}}$ , the value of the multiplier  $\lambda = \sigma[\|\mathbf{x} + \mathbf{o}\|_{\mathbf{M}}^2 + \epsilon]^{p/2-1}$ , the number of Newton steps required to find  $\lambda$ , and the exit code from this calculation (0 = successful, 1 = stalled, 2 = more than 100 steps). If `control%print_level  $\geq$  2`, this output will be increased to provide significant detail of each iteration. This extra output includes a complete history of the inner iteration required to solve the “tridiagonal” subproblem, and for each Newton iteration records the estimate of  $\lambda$ , the error  $\theta(\lambda) = \|\mathbf{x} + \mathbf{o}\|_{\mathbf{M}}^2 + \epsilon]^{p/2-1} - \lambda/\sigma$  and the  $\mathbf{M}$ -norm of  $\mathbf{x}$ .

## 3 GENERAL INFORMATION

**Use of common:** None.

**Workspace:** Provided automatically by the module.

**Other routines called directly:** `GLRT_solve` calls the LAPACK subroutine `*PTTRF`, where `*` is `S` for the default real version and `D` for the double precision version.

**Other modules used directly:** `GLRT_solve` calls the GALAHAD packages `GALAHAD_SYMBOLS`, `GALAHAD_SPACE`, `GALAHAD_RAND`, `GALAHAD_NORMS`, `GALAHAD_GLTR`, `GALAHAD_ROOTS` and `GALAHAD_SPECFILE`.

**Input/output:** Output is under control of the arguments `control%error`, `control%out` and `control%print_level`.

**Restrictions:**  $n > 0$ ,  $\sigma > 0$ .

**Portability:** ISO Fortran 95 + TR 15581 or Fortran 2003. The package is thread-safe.

---

**All use is subject to the conditions of a BSD-3-Clause License.**

See <http://galahad.rl.ac.uk/galahad-www/cou.html> for full details.

## 4 METHOD

The required solution  $\mathbf{x}$  necessarily satisfies the optimality condition  $\mathbf{H}\mathbf{x} + \lambda\mathbf{M}\mathbf{x} + \mathbf{c} + \lambda\mathbf{o} = 0$ , where  $\lambda = \sigma[\|\mathbf{x} + \mathbf{o}\|_{\mathbf{M}}^2 + \varepsilon]^{p/2-1}$ . In addition, the matrix  $\mathbf{H} + \lambda\mathbf{M}$  will be positive semi-definite.

The method is iterative. Starting with the vector  $\mathbf{M}^{-1}\mathbf{c}$ , a matrix of Lanczos vectors is built one column at a time so that the  $k$ -th column is generated during iteration  $k$ . These columns span a so-called Krylov space. The resulting  $n$  by  $k$  matrix  $\mathbf{Q}_k$  has the property that  $\mathbf{Q}_k^T \mathbf{H} \mathbf{Q}_k = \mathbf{T}_k$ , where  $\mathbf{T}_k$  is tridiagonal. An approximation to the required solution may then be expressed formally as

$$\mathbf{x}_{k+1} = \mathbf{Q}_k \mathbf{y}_k$$

where  $\mathbf{y}_k$  solves the “tridiagonal” subproblem of minimizing

$$\frac{1}{2} \mathbf{y}^T \mathbf{T}_k \mathbf{y} + \|\mathbf{c}\|_{\mathbf{M}^{-1}} \mathbf{e}_1^T \mathbf{y} + \frac{1}{p} \sigma[\|\mathbf{y} + \mathbf{d}\|_2^2 + \varepsilon]^{p/2}, \quad (4.1)$$

where  $\mathbf{d} = \mathbf{Q}_k^T \mathbf{M} \mathbf{o}$  and  $\mathbf{e}_1$  is the first unit vector.

To minimize (4.1), the optimality conditions

$$(\mathbf{T}_k + \lambda \mathbf{I}) \mathbf{y}(\lambda) = -\mathbf{c} - \lambda \mathbf{d}, \quad (4.2)$$

where  $\lambda = \sigma[\|\mathbf{y}(\lambda) + \mathbf{d}\|_{\mathbf{M}}^2 + \varepsilon]^{p/2-1}$  are used as the basis of an iteration. Specifically, given an estimate  $\lambda$  for which  $\mathbf{T}_k + \lambda \mathbf{I}$  is positive definite, the tridiagonal system (4.2) may be efficiently solved to give  $\mathbf{y}(\lambda)$ . It is then simply a matter of adjusting  $\lambda$  (for example by a Newton-like process) to solve the scalar nonlinear equation

$$\theta(\lambda) \equiv [\|\mathbf{y}(\lambda) + \mathbf{d}\|_{\mathbf{M}}^2 + \varepsilon]^{p/2-1} - \frac{\lambda}{\sigma} = 0. \quad (4.3)$$

In practice (4.3) is reformulated, and a more rapidly converging iteration is used.

It is possible to measure the optimality measure  $\|\mathbf{H}\mathbf{x} + \lambda\mathbf{M}\mathbf{x} + \mathbf{c} + \lambda\mathbf{o}\|_{\mathbf{M}^{-1}}$  without computing  $\mathbf{x}_{k+1}$ , and thus without needing  $\mathbf{Q}_k$ . Once this measure is sufficiently small, a second pass is required to obtain the estimate  $\mathbf{x}_{k+1}$  from  $\mathbf{y}_k$ . As this second pass is an additional expense, a record is kept of the optimal objective function values for each value of  $k$ , and the second pass is only performed so far as to ensure a given fraction of the final optimal objective value. Large savings may be made in the second pass by choosing the required fraction to be significantly smaller than one.

Special code is used in the special case  $p = 2$ , as in this case a single pass suffices.

**Reference:** The method is described in detail in

C. Cartis, N. I. M. Gould and Ph. L. Toint, Adaptive cubic regularisation methods for unconstrained optimization. Part I: motivation, convergence and numerical results. *Mathematical Programming* **127**(2), pp.245-295, 2011.

## 5 EXAMPLE OF USE

Suppose we wish to solve a problem in 10,000 unknowns, whose data is

$$\mathbf{H} = \begin{pmatrix} -2 & 1 & & & \\ 1 & -2 & & & \\ & & \ddots & & \\ & & & -2 & 1 \\ & & & 1 & -2 \end{pmatrix}, \quad \mathbf{M} = \begin{pmatrix} 2 & & & & \\ & 2 & & & \\ & & \ddots & & \\ & & & 2 & \\ & & & & 2 \end{pmatrix}, \quad \mathbf{c} = \begin{pmatrix} 1 \\ 1 \\ \vdots \\ 1 \\ 1 \end{pmatrix} \quad \text{and} \quad \mathbf{o} = -\begin{pmatrix} 1 \\ 1 \\ \vdots \\ 1 \\ 1 \end{pmatrix},$$

with a weight  $\sigma = 10$  and shift  $\varepsilon = 1$ . Suppose further that we are content with an approximation which is within 99% of the best. Then we may use the following code
